

Data Assimilation in a high-resolution, sub-mesoscale regional model of Hawaii

Dax Matthews and Brian Powell

April 7, 2010

ROMS Workshop

UNIVERSITY
of HAWAII®
MĀNOA

Objectives

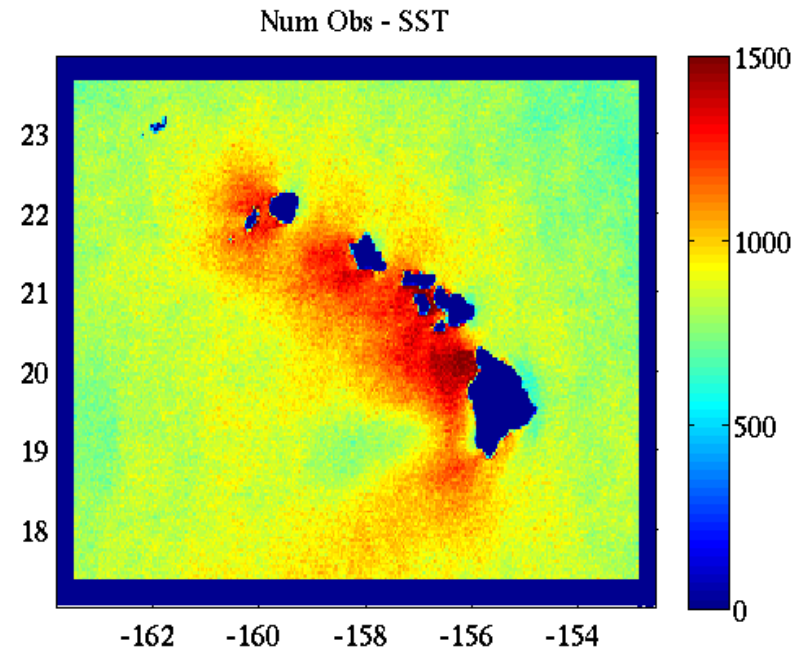

- Utilize IS4DVAR method to study circulation and dynamics around Hawaiian Islands
- Spin-up for near-realtime operational system (HIOOS)
www.soest.hawaii.edu/hioos
- Evaluate assimilation system configuration
 - Obs/Model misfit
 - Overall Assimilation/NLM differences
 - Comparison with independent observations

ROMS Configuration

- 4 km horizontal resolution
- 30 sigma levels
- 4 open boundaries setup to conserve volume
- Boundary Conditions and Climatology
 - 1/8° global Naval Coastal Ocean Model (NCOM)
- Forcing
 - NCEP reanalysis with mm5 cora blend winds (NHI)
 - Jan 2008 to May 2009
 - Weather Research and Forecasting (WRF) Model
 - May 2009 to Dec 2009

Observations

- Satellite Radiometry
 - Sea surface temperature (SST) - AVHRR-18, MODIS Aqua, MODIS Terra
 - LAC/HRPT 1.1 km resolution swath data
- Satellite Altimetry
 - Along-track Sea level anomalies (SLA) - Jason-1, Jason-2, Envisat and GFO
 - ~18 km resolution
 - AVISO does not release 1 Hz data in realtime
- Argo
 - Array of temperature/salinity free drifting profiling floats
- Gliders
 - Autonomous underwater vehicle
 - Temperature/salinity profiles
 - Short data sets due to ???
- Hawaii Ocean Time series (HOT) Cruises
 - CDT (conductivity, temperature, depth) profiles
 - ADCP (acoustic Doppler current profiler) velocity profiles
- Surface Drifters
 - Satellite tracked surface (15-m drogue) buoys estimate current velocity

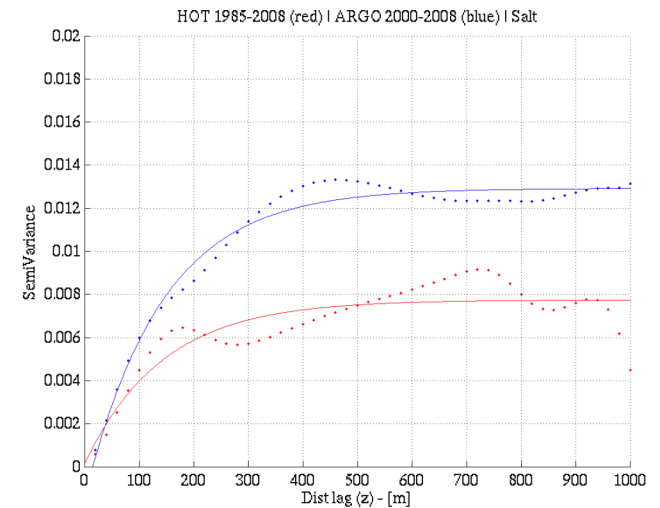

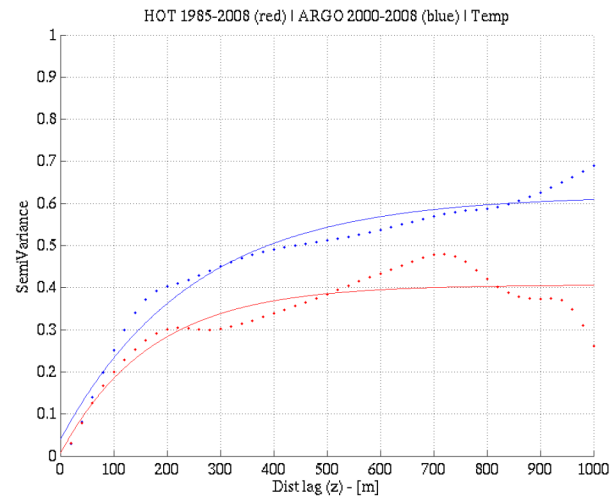

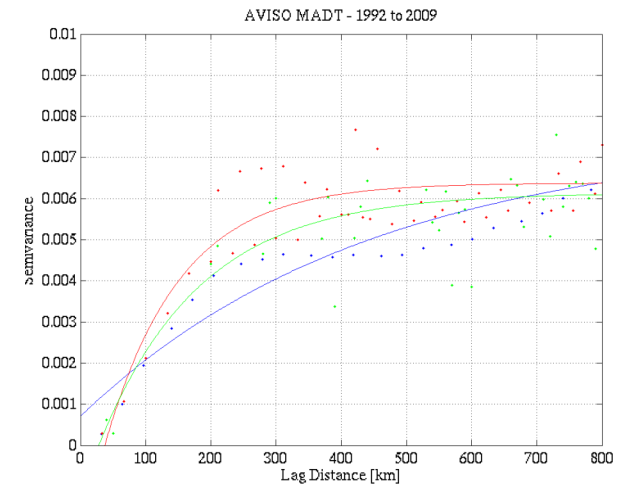

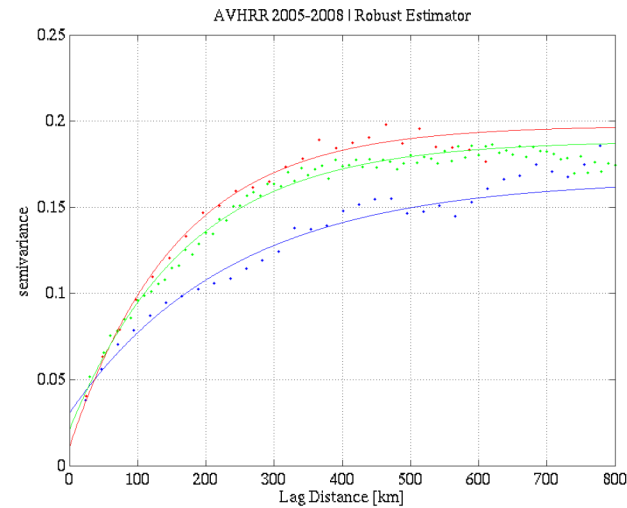

Number of Observations

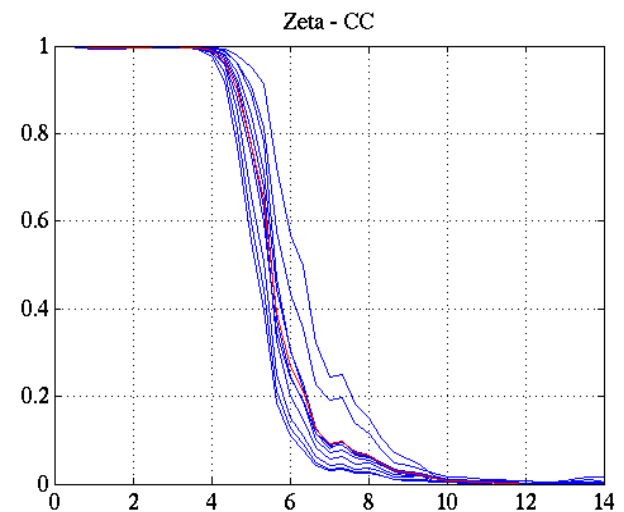

IS4DVAR Setup

- 6-year run forward model reference mean and variance of model state
- # of loops
 - Cycle 1-4
 - 1 outer loop and 50 inner loops
 - Cycle 5-8
 - 25 inner loops
 - Cycle 9-117
 - 20 inner loops
- Length scales
 - 200 km horizontal
 - 200 m vertical

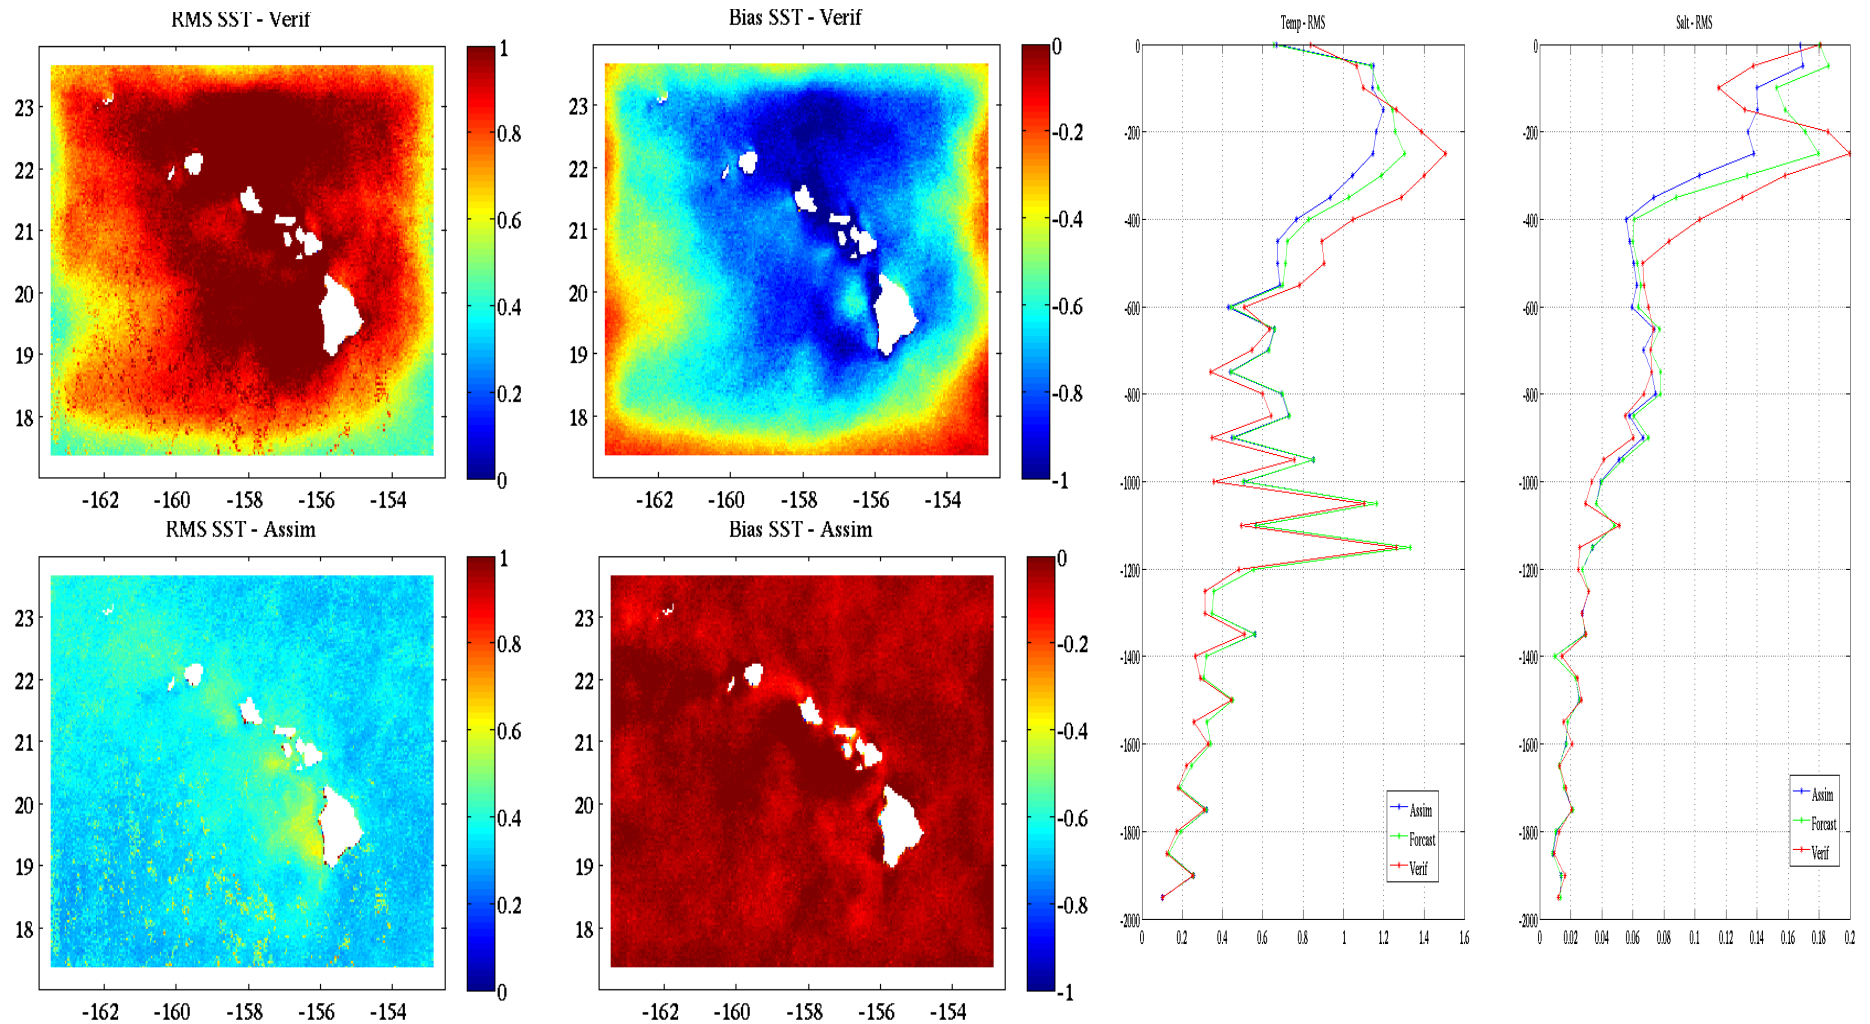

Tangent Linear Assumption

- 7-day assimilation cycle w/ 1-day overlap
- Test:
 - use MTLM and Gram-Schmidt orthogonalization to generate ensemble of perturbations to propagate through TLM and NLM
 - Correlation of NLM and TLM
- Result: 7-day runs suboptimal, however should invalidate assimilation

- Reduction of overall observation-model misfit by over 65%
- Reduction of SST RMSE by ~68%
- SSH RMSE reduction only ~9%
- At shallow depths (less than 100m) high assimilation RMSE in temperature and salinity compared to forward model
- In 150-500m reduced assimilation RMSE compared to forward model

Time series of daily RMS differences and bias (obs – model) for SST and SSH.

Mean SST

STD SST

Mean Currents

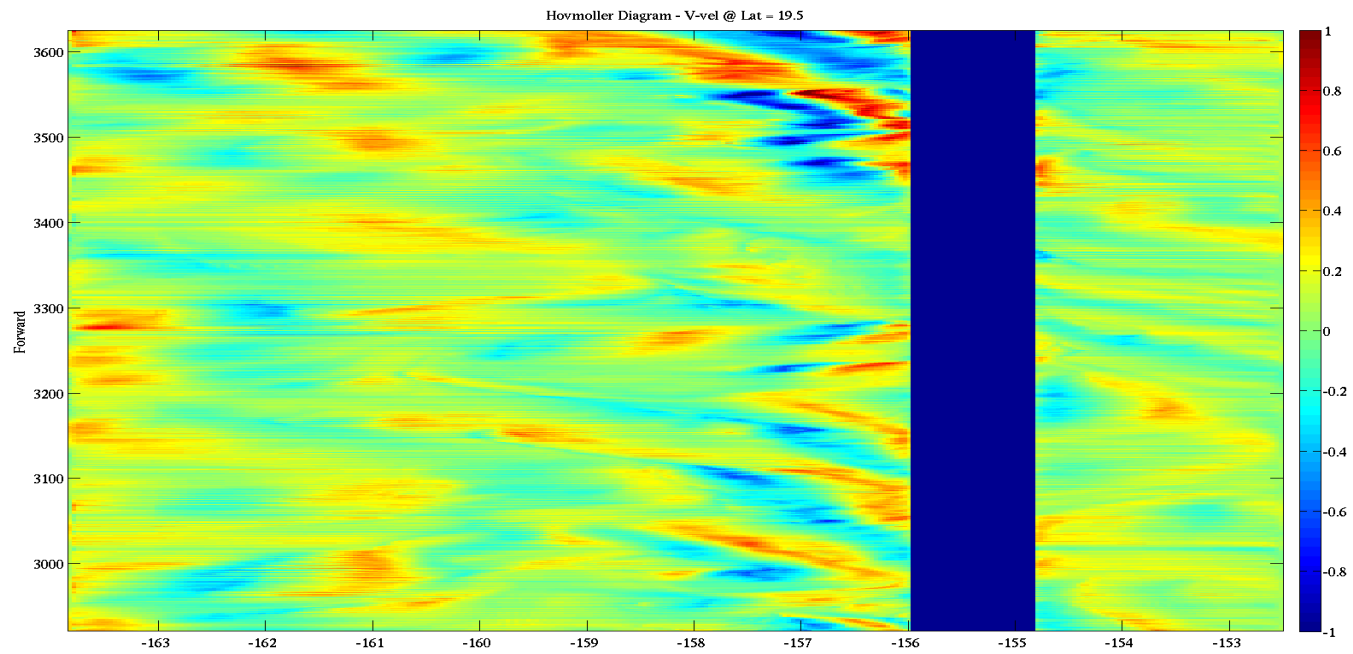

Mean Current Mag

EKE

Hovmoller Diagram - U-vel @ Lon = -158

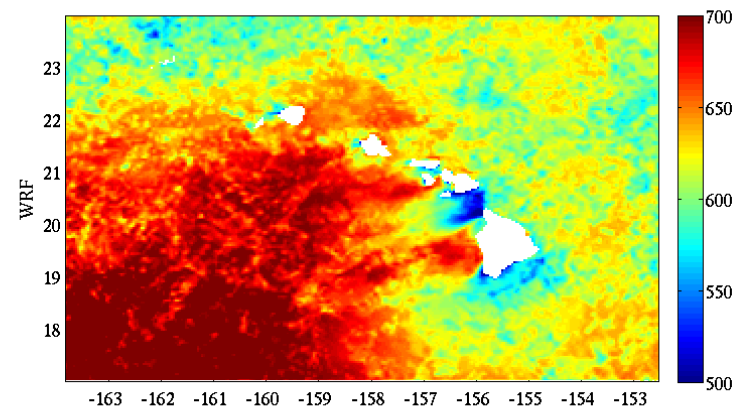

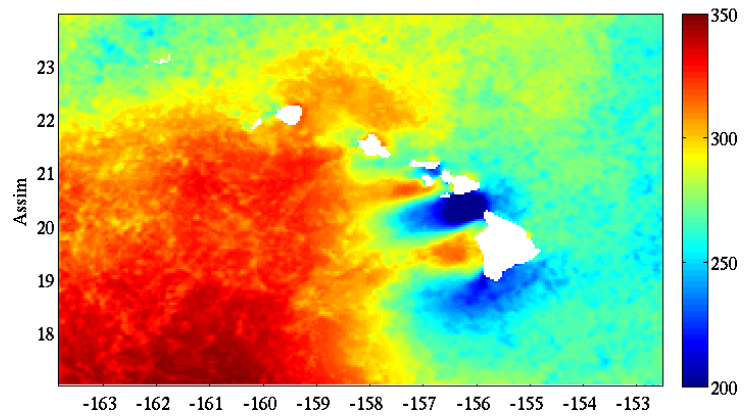

Mean Salt Flux

Mean Diff SSS (assim - verif)

Future Work

- Switch to 1Hz PO.DAAC IGDR
- Test limiting number of SST obs
- Correct heat flux/hot bias
- Correct assimilation cycle length
- Introduce tides to system
- Obs impact study
